# CATS EMERGENCY INTUBATION CHECKLIST

### Prepare for difficulty

**Is a difficult airway anticipated?**
- History of previous difficult intubation
- Stridor
- Large tongue/tonsils/tumour
- Restricted jaw/neck movement
- Prominent upper teeth
- Small receding jaw
- Syndrome/Diagnosis associated with airway difficulty eg. Pierre-Robin, Hurler's
- **No**
- **Yes:** call consultant

Discuss strategies for dealing with difficult intubation or mask ventilation (see DAS guidelines)

**Are complications anticipated?**
- **No**
- **Yes:** discuss management strategy

Identify who to contact in an emergency. Do they need to be pre-warned?
- **No**
- **Yes**

### Prepare Equipment

**Apply monitoring**
- ECG
- Blood pressure (1 min auto)
- SpO2 probe (audio)
- Capnography

**Check Equipment (BOX A + B)**
- Mask
- Guedel airway(s)
- T-piece & oxygen supply
- Suction
- ET tubes (+/- sizes)
- Laryngoscope x2
- Equipment for alternative plans—bougie, LMA, alt. blade
- Tapes
- Bag Valve Mask

**Prepare Drugs (CHART C)**
- Induction agent/analgesic
- Muscle relaxant
- Drugs for circulatory support (fluid bolus, vasoactive drugs, atropine)
- Maintenance sedation

### Prepare Patient

- **Confirm IV access is patent**

- **Is pre-oxygenation optimal?**
- **Optimise patient’s position (consider pillow)**

- **Does an NG tube need to be inserted or aspirated?**

- **Could the patient’s condition be optimised further before intubation?**

### Prepare Team

Intubation should be a two-doctor/ANP task. Are two appropriately experienced people present?
- **No**, find a second intubator
- **Yes**

Are any additional staff required?

**Allocate Roles**
- Intubator
- Intubator’s Assistant
- Monitoring/Drugs

- **Ready to proceed?**

---

**Disclaimer** - The information provided on this checklist is intended as guidance only and is not intended to be a comprehensive guide to preparation for intubation. Conduct in individual cases should be determined by the facts pertaining to that case and should be confirmed by a specific risk assessment in each situation.

---

Children’s Acute Transport Service provides paediatric intensive care retrieval for Great Ormond Street, The Royal Brompton and St Mary’s NHS Trusts. Funded and accountable to the North Thames Paediatric Intensive Care Commissioning Group through Great Ormond Street NHS Trust.

CHART C

**Assessment**

**Complete CATS Emergency Intubation Checklist**

**Difficult airway:** refer to algorithm and involve ENT

**Cardiovascular instability:** appropriate induction agent and prepare inotrope(s) + fluid bolus

**Induction agent**

**Ketamine 1-2mg/kg or Fentanyl 2-5mcg/kg**

**Neuromuscular blockade**

**Rocuronium 1mg/kg or Suxamethonium 1-2mg/kg**

---

Children's Acute Transport Service provides paediatric intensive care retrieval for Great Ormond Street, The Royal Brompton and St Mary's NHS Trusts. Funded and accountable to the North Thames Paediatric Intensive Care Commissioning Group through Great Ormond Street NHS Trust.
General aspects

Note that administering a general anaesthetic in an unfamiliar environment (i.e. a referring hospital) should be a two-doctor procedure, involving a local anaesthetist with appropriate skill.

If difficulty is anticipated, a consultant anaesthetist should be involved and it may be appropriate to move the child to theatres with suitable equipment and staffing.

Approach all intubations with caution as it is impossible to exclude difficulty by examination.

Assessment:
Management of the difficult airway should proceed along guidelines from the APA (Association of Paediatric Anaesthetists) management of difficult airways in children. **Involves the ENT team early if problems are anticipated.**
http://www.das.uk.com/guidelines/paediatric-difficult-airway-guidelines

Inhalational agents and anaesthetic machines should only be used by doctors trained in their use.

Induction agent:

- Fentanyl or ketamine are the agents of choice in children with cardiovascular instability and may be used in all age groups
- For the unstable neonate an opiate-only technique may be used – fentanyl is preferable
- Etomidate has minimal cardiovascular effects but may cause adrenal insufficiency in critically unwell patients

Several studies have demonstrated that ketamine does not cause any significant rise in intracranial pressure, so is a safe induction agent to use in cases of raised ICP e.g. Meningitis/encephalitis, traumatic brain injury or space occupying lesion.

Thiopentone and propofol **may** be used for induction, but should not be used in critically unwell children with cardiovascular compromise as they can cause profound hypotension.

Neuromuscular blockade in Rapid Sequence Induction:

- Suxamethonium (1-2mg/kg) has a rapid onset (30 seconds) and short duration of action (3-5mins)
- Rocuronium given at a dose of 1mg/kg provides neuromuscular blockade within 30-45 seconds with a longer duration of action (30-40 mins)

Suxamethonium is contraindicated in patients with hyperkalaemia, muscular dystrophy, myotonia, spinal cord injuries, after 24 hours of major burns and in those at risk of malignant hyperpyrexia. It may also cause bradycardia, so if used, atropine should be readily available.
Sugammadex can be used for the reversal of aminosteroid neuromuscular blockade agents (rocuronium and vecuronium).

- Immediate reversal of rocuronium with sugammadex – 16mg/kg

**Ongoing sedation**

Note that midazolam may cause hypotension in children with cardiovascular instability.

Prolonged propofol infusions are not recommended in children due to the risk of propofol infusion syndrome.

**Intubation**

As a group, the paediatric intensive care population is intolerant of low pressure endotracheal leak.

- Stiff lungs need high positive end expiratory pressure (PEEP)
- Higher peak airway pressures may be required
- Gas consumption for PEEP on transport needs to be minimised

It is also desirable to minimise the number of re-intubations, especially in the early emergency/stabilisation phase.

In general for emergency referrals to CATS we would suggest the use of a cuffed endotracheal tube and if changing a tube due to leak we would replace with a cuffed one.

**Sizing**

**Internal diameter (ID)**

Khine Formula: \[ \text{ID}(\text{mm}) = \frac{\text{age}}{4} + 3.0 \] <2yrs

Motoyama formula: \[ \text{ID}(\text{mm}) = \frac{\text{age}}{4} + 3.5 \] > 2yrs

**Cuff pressure**

Inflate to just obliterate leak

Ideally <20 cm H$_2$O pressure in cuff using cuff manometry

**Depth (CXR confirmation vital)**

\[
\text{length (cm)} = \begin{cases} 
\text{Oral} & (\text{age}/2 + 12) \\
\text{Nasal} & (\text{age}/2 + 15)
\end{cases}
\]

**Complications and hazards**

- Avoid use of cuffed endotracheal tube with internal diameter <3.0mm
- The ‘black line’ as a guide to depth: this may result in inadvertent endobronchial intubation
- Avoid laryngeal cuff placement
- Monitor cuff pressures (manometer) and consider the relative risks of cuff pressure on tracheal perfusion in low cardiac output states

**Transport considerations**

- Aeromedical transports: A climb in altitude will increase cuff pressure and this should be monitored/adjusted until cruise altitude. Consider using water to fill cuff

**Key messages**

- PICU children may require higher peak and positive end expiratory pressures than would be routine in elective anaesthesia
- With a cuffed endotracheal tube it is possible to compensate for a slightly ‘small’ endotracheal tube or a patient with deteriorating lung compliance and increasing airway pressure requirements

**If in doubt discuss with duty CATS consultant.**
