Septic Shock

Septic shock is suspected when children have a change in mental status manifested as irritability, inappropriate crying, drowsiness, confusion, poor interaction with parents, lethargy, or becoming unrousable, along with additional features such as tachypnoea and reduced urine output.

Recognition

- Suspected infection
- Hypo or hyperthermia (temp <36° or >38.5°) tachycardia
- Tachypnoea
- Altered mental status
- Decreased urine output (<1 ml/kg/hr) other end organ dysfunction
- Signs of either cold or warm shock

For recognition of a child at risk refer to the amber and red signs on the Paediatric Sepsis 6 trigger bundle at the end of the guideline.

</table>

Hypotension is not required for the clinical diagnosis of shock; however once it is present in a child with a suspected infection the diagnosis is confirmed. Early signs and symptoms of shock are as a result of the body’s compensatory mechanisms, while late signs are indicative of decompensation.

There is evidence showing aggressive optimisation of the haemodynamic status within the first few hours of critical illness reduces subsequent organ failure improving overall survival. Paediatric septic shock is typically associated with severe hypovolemia and children frequently respond well to aggressive volume resuscitation, children are consistently under-resuscitated in the first few hours. For every hour that a child remains in septic shock the mortality risk doubles.

**The first hour of resuscitation – Goals to restore**

- Normal perfusion
- No difference in quality between central & peripheral pulses
- Warm extremities
- Capillary refill time <2s
- Normal range for age heart rate, blood pressure & respiratory rate for age (this may not be possible if the underlying cause is pneumonia)
- Normal mental status
- Urine output >1ml/kg/hr
- Serum lactate < 2
- ScvO2 sats (where available) >70%
- Normal glucose and ionized calcium concentrations

**Actions in the 1st hour**

- Maintain or restore a patent airway
- High flow oxygen to achieve saturations >95% - intubate if indicated
- Obtain secure intravenous or intraosseous access x2
- Give high dose broad spectrum antibiotics- avoid ceftriaxone (<1yr) due to risk of precipitation with calcium administration, use cefotaxime
Do not waste valuable time - if difficult IV access, site an intraosseous (IO) needle. More than one is frequently required.

**Resuscitate**

Signs of shock should be *immediately* treated

- 20 mls/kg over 5 minutes. Rapid infusion bolus administered either by push or pressure bag
- Use 0.9% Saline or Human Albumin Solution 4.5% (HAS)
- Correct hypoglycaemia, give 2 mls/kg of 10% Glucose

**Reassess - What are the effects of every fluid bolus?**

- Have the heart rate, quality of peripheral pulses, CRT, mental state, blood pressure responded? Multiple fluid boluses may be necessary
- Large fluid deficits often exist & initial fluid volumes of 40-60 ml/kg are quite usual, volumes of 80-100mls/kg may be necessary
- Is there evidence of volume overload? (hepatomegaly, crackles, increased work of breathing or gallop rhythm), fluid is not recommended when rales or hepatomegaly are present – commence inotropic support

If after **15 minutes of optimal fluid resuscitation** (40-60 mls/kg) and there is still evidence of end organ dysfunction start peripheral or IO **Adrenaline** at 0.1mcg/kg/min up to 0.5mcg/kg/min.

Refer to CATS at this point if not already done so.

**Inotrope choice:**

- Adrenaline for COLD SHOCK
- Noradrenaline for WARM SHOCK

**Hydrocortisone Therapy**

- If in catecholamine resistant shock then IV hydrocortisone should be administered at 1mg/kg qds (2.5mg/kg in neonates)

**Obtain central access**

**Insert an arterial line for haemodynamic monitoring**

**Indications for Intubation**

- Impending cardiovascular collapse
- Poor airway reflexes
- Depressed level of consciousness -Glasgow Coma Score (GCS) ≤ 8 or AVPU ≤ P worsening tachypnoea or oxygen requirement
Fluid refractory shock (≥ 40 mls/kg fluid resuscitation in the first 30 minutes without reversal of shock)

Management of intubation

- Optimal volume replacement prior to intubation
- Fluid bolus attached prior to induction drugs
- Adrenaline infusion drawn up and attached if not running
- Pre oxygenation with 100% O₂
- A “good fit” ETT (preferably a cuffed ETT). This is necessary to ventilate in the presence of pulmonary oedema
- Ensure the most experienced team members perform the intubation
  Anaesthetic / ICU Consultant with Paediatric Consultant support
- Use of optimal drugs for induction (refer to CATS intubation checklist)
- Modified rapid sequence induction (cricoid pressure)

Inhalational anaesthetics present a significant risk of cardiovascular depression. They should only be used if the risk of a difficult airway outweighs this. Thiopentone, propofol & benzodiazepines all carry a similar risk of significant cardiovascular depression.

Once Intubated

- End tidal CO₂ monitoring is mandatory
- Secure ETT – do not cut the ETT
- Check appropriate position with CXR (Tip at T2-T3)
- Sedate & muscle relax as per CATS guidelines
- These children are at risk of acute respiratory distress syndrome (ARDS). A low tidal volume strategy of 4-7 ml/kg with an initial PEEP of 5 cm/H₂O should be used. PEEP can be titrated up depending on blood gases & evidence of pulmonary oedema

Stabilisation

Coagulopathy

- Consider treatment with 10-20 mls/kg of Fresh Frozen Plasma (FFP)
- Low platelet counts in the absence of active bleeding should not be supplemented unless < 20 x10⁶/microlitre
- Low fibrinogen is suggestive of DIC give 5-10mls/kg of Cryoprecipitate

Electrolytes

- Treat Hypocalcaemia (0.5 mls/kg 10% calcium gluconate)
- Treat Hypomagnesaemia 0.5 ml/kg 20% magnesium sulphate (or 1ml/kg 10% magnesium sulphate)

(This can cause hypomagnesaemia, give slowly over 30 minutes with additional fluid bolus if necessary)
Ongoing Fluid Resuscitation

Fluid shift and hypotension secondary to capillary leak can continue for several days. Continued fluid administration should be titrated against clinical end points such as, heart rate, perfusion pressure, cardiac output, urine output, serum lactate and ScvO₂ saturations.

Consider Fresh Frozen Plasma for coagulopathy. Consider packed red cells.

Indicators of disease severity

- Low neutrophils
- Low platelets
- Rapid onset (<6 hours)
- Rapidly spreading rash
- High volume requirement

References:

Paediatric Sepsis 6

Recognition of child at risk
if a child with suspected or proven infection AND at least 2 of:
- Core temperature of <36°C or >38.5°C (38.0°C if immunocompromised)
- Tachycardia (refer to Early Warning Score)
- Altered mental state (dipsiness, irritability, lethargy, floppiness)
- Prolonged capillary refill (> 2s)
- Immunocompromised
- Hypotension

Red flag signs (Any 1 flag present)
- Lactate >2mmol/l
- Extreme tachycardia/tachypnoea
- SpO2 <90%/grunting/cyanosis/apnoea
- P or U on AVPU
- Persistent hypotension (2x consecutive measurements in 1hr)
- Non blanching rash/mottled skin

CONSULT DOCTOR OR SENIOR STAFF MEMBER – COULD THIS CHILD HAVE SEPSIS OR SEPTIC SHOCK?

START TIME

Yes or high suspicion – start Sepsis 6
1) Give high flow oxygen Time Sign
2) Obtain IV/IO access and take blood tests Time Sign
- Blood gas and lactate (+/- FBC, U&E, CRP if able)
- Blood glucose – treat hypoglycaemia (2mM/l 10% glucose)
- Blood cultures
3) Give IV or IO antibiotics Time Sign
4) Consider fluid resuscitation Time Sign
- Aim to restore normal physiological parameters, U/O >0.5mL/kg/hr
- Give 10:20mL/kg isotonic fluid over 5-10 mins
- Repeat as necessary, monitor urine output
5) Involve senior clinicians early Time Sign
- Own team Consultant
6) Consider inotropic support early Time Sign
- If normal physiological parameters not restored after 40mL/kg fluids consider CATS referral. Ring Hotline no. 0800 085 0003

Comence all elements within 1 hour

END TIME

No or unsure
Review hourly and document below
- Not sepsis – document reasons Time Sign
- Unsure – review within 1 hour
- REVIEW WITHIN 1 HOUR (Repeat obs every 30min)
- Not sepsis – document reasons Time Sign
- Unsure – review within 1 hour
- REVIEW WITHIN 1 HOUR (Repeat obs every 30min)
- Sepsis – start Sepsis 6
- Not sepsis – document reasons Time Sign
- Sepsis – start Sepsis 6
- Unsure – review within 1 hour
- REVIEW WITHIN 1 HOUR (Repeat obs every 30min)
- Not sepsis – document reasons Time Sign
- Sepsis – start Sepsis 6
- Unsure – review within 1 hour
- REVIEW WITHIN 1 HOUR (Repeat obs every 30min)

Is there a likely source of infection?
- Yes, but source unclear at present
- Line infection
- Meningitis/encephalitis
- Febrile Neutropenia
- Line infection
- Intra-abdominal
- Urinary tract infection
- Other – details

Any questions, please contact Claire Fraser (Claire.fraser@gnh.nhs.uk) or Rhiannon Folley (Rhiannon.Folley@gnh.nhs.uk)

Adapted from the Paediatric Sepsis version 6.1.1 August 2015 in collaboration with the UK Sepsis Trust Paediatric Group

1.

Children’s Acute Transport Service provides paediatric intensive care retrieval for Great Ormond Street, The Royal Brompton and St Mary’s NHS Trusts. Funded and accountable to the North Thames Paediatric Intensive Care Commissioning Group through Great Ormond Street Hospital.
Recognize decreased mental status and perfusion. Begin high flow O₂ and establish IO/IV access according to PALS.

If no hepatomegaly or rales / crackles then push 20 mL/kg isotonic saline boluses and reassess after each bolus up to 60 mL/kg until improved perfusion. Stop for rales, crackles or hepatomegaly. Correct hypoglycemia and hypocalcemia. Begin antibiotics.

**Fluid refractory shock?**

Begin peripheral IV/IO inotrope infusion, preferably Epinephrine 0.05 – 0.3 μg/kg/min
Use Atropine / Ketamine IV/IO/IM if needed for Central Vein or Airway Access

Titrate Epinephrine 0.05 – 0.3 μg/kg/min for Cold Shock.
(Titrate central Dopamine 5 – 9 μg/kg/min if Epinephrine not available)
Titrate central Norepinephrine from 0.05 μg/kg/min and upward to reverse Warm Shock.
(Titrate Central Dopamine ≥ 10 μg/kg/min if Norepinephrine not available)

**Catecholamine-resistant shock?**

If at risk for Absolute Adrenal Insufficiency consider Hydrocortisone.
Use Doppler US, PICCO, FATD or PAC to Direct Fluid, Inotrope, Vasopressor, Vasodilators
Goal is normal MAP-CVP, ScvO₂ > 70%* and CI 3.3 – 6.0 L/min/m²

**Persistent Catecholamine-resistant shock?**

Evaluate Pericardial Effusion or Pneumothorax, Maintain IAP < 12mmHg

**Refractory Shock?**

ECMO
