Supraventricular Tachycardia

Definition
Supraventricular tachycardia is broadly defined as a narrow, complex tachycardia that requires atrial tissue or the atrioventricular node as an integral part of the arrhythmia substrate. Typical features:

- Heart rate >220
- Narrow complex, regular tachycardia (no beat by beat variability)
- If present, p waves are seen before every QRS complex

Aetiology
Most tachyarrhythmia in children are due to congenital re-entrant pathways but some are secondary to infection, poisoning, metabolic disturbance, following cardiac surgery, or cardiomyopathy.

1. Assessment

History
- Onset
- Associated pain, dyspnoea, syncope or dizziness
- Infants – poor feeding, pallor, tachypnoea, irritability
- Older children – palpitations, chest discomfort
- Medication
- PMH – Congenital cardiac problems/surgery
- Sometimes diagnosed antenatally (atrial flutter)

Clinical Assessment
- Airway and breathing
- Circulation
  - ECG strip and 12 lead ECG
  - Assess for signs of cardiogenic shock
    - Prolonged CRT
    - Low BP
    - Acidotic blood gas
    - Gallop rhythm
    - Enlarged liver
  - Discuss with cardiology team early
- Disability
  - Agitation, confusion
- Exposure
  - Rule out other causes of presentation (as above)
- Electrolytes
  - Check electrolytes (including Mg, PO4, Ca, K)
  - Check drug levels (if on theophylline or digoxin)
- Infection
  - May be a presenting feature of myocarditis
  - Consider antibiotics in neonates

2. Immediate management

- Vagal manoeuvres
  - Diving reflex
  - One sided carotid sinus massage
  - Valsalva manoeuvre in older child
- Follow APLS algorithm below (Have ECG strip monitoring attached and printing if possible)

IF ADENOSINE FAILS, DISCUSS WITH PAEDIATRIC CARDIOLOGIST.

Further options:

Assume cardiac dysfunction is present

- Amiodarone has a negative inotropic effect and may compromise cardiovascular state
- Amiodarone infusion, usually start at 25mcg/kg/min for 4 hours and then reduce to 10-15mcg/kg/min
- Cardiology may suggest alternative agents such as a beta-blocker
- +/- elective DC cardioversion

Indications for intubation (see CATS Intubation guideline)

- Adenosine resistant SVT – need for DC cardioversion
- Cardiac failure with acidosis
- Impending cardiorespiratory collapse

Intubation

- Use cardiostable induction agents (see CATS Intubation guideline)
- Inotropic agents to be available in case of deterioration during/post-intubation
3. Management following intubation

- Sedate and use muscle relaxation
- Correct acidosis – give cautious fluid boluses of 10ml/kg, consider bicarbonate and inotropic support (be aware that inotropes may precipitate further dysrhythmias – discuss use with CATS consultant)
- Continue to liaise with the paediatric cardiologist

**Intractable SVT**

If SVT is intractable and associated with severe acidosis, consider transport to an ECMO centre for further support (discuss with CATS consultant and ECMO Consultant).
Children’s Acute Transport Service provides paediatric intensive care retrieval for Great Ormond Street, The Royal Brompton and St Mary’s NHS Trusts. Funded and accountable to the North Thames Paediatric Intensive Care Commissioning Group through Great Ormond Street NHS Trust.
